Topic	Interpretation
<p><b>Constrained Optimization:</b> Suppose <math>f(x,y)</math> has to be minimized or maximized subject to the constraint <math>g(x,y) = 0</math> Use the Lagrange Multipliers: 1.)Set: <math>L(x,y, \lambda) = f(x,y) - \lambda g(x,y)</math> 2.)Find <math>x</math> and <math>y</math> as solutions of: <math>\frac{\partial L}{\partial x} = 0, \frac{\partial L}{\partial y} = 0, g(x,y) = 0</math> <u>Example1:</u> Use the Lagrange multiplier to find the values of <math>x</math> and <math>y</math> which maximizes <math>160x - 3x^2 - 2xy - 2y^2 + 120y - 18</math> subject to the constraint <math>x + y = 34</math> <i>NB</i> : If no constraint is imposed The maximum is at <math>(20,20)</math> <math>f_1 = 160 - 6x - 2y = 0</math> <math>f_2 = -2x - 4y + 120 = 0</math> Solving simultaneously, <math>x = 20</math> <math>y = 20 ; f_{11} = -6, f_{22} = -4; f_{12} = -2</math> <math>\Rightarrow (f_{11})(f_{22}) - f_{12}^2 = 20 &gt; 0</math> Since <math>f_{11} = -6 &lt; 0 \Rightarrow (20,20)</math> maximizes <math>f</math>. <b>Applications of Constrained Optimization:</b> <b>1. Utility Function: <math>u(x,y)</math> :</b> For consuming two goods <math>X</math> and <math>Y</math>, <math>u(x,y)</math> enables deciding between two bundles, i.e. ranking bundles.</p>	<p><math>f(x,y) = 160x - 3x^2 - 2xy - 2y^2 + 120y - 18;</math> <math>g(x,y) = x + y - 34 = 0</math> <math>L(x,y, \lambda) = f(x,y) - \lambda g(x,y)</math> <math>L = 160x - 3x^2 - 2xy - 2y^2 + 120y - 18 - \lambda(x + y - 34)</math> <math>L = (160 - \lambda)x - 3x^2 - 2xy - 2y^2 + (120 - \lambda)y - 18 + 34\lambda</math> <math>\frac{\partial L}{\partial x} = 160 - \lambda - 6x - 2y = 0 \text{ -----(1)}</math> <math>\frac{\partial L}{\partial y} = -2x - 4y + 120 - \lambda = 0 \text{ ----(2)}</math> <math>g(x,y) = x + y - 34 = 0 \text{ -----(3)}</math> Eliminate <math>\lambda</math> from (1) &amp; (2) : (1) <math>\lambda = 160 - 6x - 2y</math> (2) <math>\lambda = -2x - 4y + 120 ; \lambda = \lambda</math> <math>160 - 6x - 2y = -2x - 4y + 120</math> <math>4x + 2y + 40 = 0 \Rightarrow 2x + y + 20 = 0 \text{ ----(4)}</math> (3) &amp; (4) : <math>x + y - 34 = 0 ; 2x + y + 20 = 0</math> <math>x = 18, y = 16</math> The constrained maximum <math>f(18,16) = 2722</math> <u>Example 2:</u> <math>u(10, 4) \succ u(9, 6)</math> means that the consumer prefers to the bundle consisting of 10 of <math>X</math> &amp; 4 of <math>Y</math> rather than 9 of <math>X</math> and 6 of <math>Y</math>. <u>Example 3:</u> The prices of two goods <math>X</math> &amp; <math>Y</math> are <math>P_x = 2</math> and <math>P_y = 5</math>. The utility function <math>u(x,y) = x^{1/3}y^{1/2}</math> and the income <math>M = 40</math>. Maximize the utility function subject to the budget constraint. The budget constraint :</p>

<p><u>Budget constraint:</u> Consumers normally seek the best bundle (highest utility-giving) they can afford. If the budget is <b>M</b> and the prices of X and Y are respectively <math>P_x</math> and <math>P_y</math>, then consumers can only afford bundles <math>(x,y)</math> satisfying: <math>xP_x + yP_y \leq M</math>. i.e. consumers tend to maximize <math>u(x,y)</math> subject to the budget constraint <math>xP_x + yP_y = M</math></p> <p><b>2. Production Function : <math>q(k,l)</math></b> <b>q : production (quantity)</b> <b>k: Capital ; l = Labour</b> In order to produce a given quantity Q ,a firm usually chooses a combination of cost units of capital and labour such that the Cost is minimum. If the cost of a unit of capital is <math>v</math> and the cost of a unit of labour (wage) is <math>w</math> then the cost is found by solving the following problem: minimize <math>vk + wl</math> subject to <math>q(k,l) = Q</math> This is again a standard Constrained Optimization problem.</p> <p><b>Production Maximization:</b> The problem here is to maximize <math>Q(x,y)</math> subject to the constraint that the company spends no more than a certain amount.</p>	<p><math>xP_x + yP_y = M ; 2x + 5y = 40</math> the problem becomes a standard <i>constrained optimization</i>: Maximize <math>u(x,y) = x^{1/3}y^{1/2}</math> subject to the constraint <math>2x + 5y = 40</math>. <i>Follow the steps mentioned in Example1</i> <math>x = 8 , y = 24/5</math> .</p> <p><u>Example 4:</u> A firm's weekly output is given by the production function <math>q(k,l) = k^{3/4} l^{1/4}</math>. The unit costs for capital and labour are <math>v = 1</math> and <math>w = 5</math> per week Find the minimum cost of producing a weekly output of 5000 and the corresponding values of <math>k</math> and <math>l</math> . The total cost : <math>vk + wl = k + 5l</math> The problem to be solved is the constrained optimization: Minimize <math>k + 5l</math> subject to <math>k^{3/4} l^{1/4} = 5000</math> <i>Follow the steps mentioned in Example1</i> <math>k = 5000(15)^{1/4} , l = 5000(15)^{-3/4}</math> Minimum cost = <math>k + 5l \approx 13120</math></p> <p><u>Example 5:</u> A firm manufactures a good from two raw materials X and Y. The quantity of its good which is produced from <math>x</math> units of X and <math>y</math> units of Y is given by the quantity <math>Q(x,y) = x^{1/4}y^{3/4}</math> If the firm spends no more than \$1280 each week on the raw material, what is the maximum possible weekly production Given that one unit of X costs \$16 and one unit of Y costs \$1 The problem here is to : Maximize <math>Q(x,y) = x^{1/4}y^{3/4}</math> subject to the constraint <math>16x + y = 1280</math> <i>Follow the steps mentioned in Example1</i> <math>x = 20 ; y = 960</math> ; Maximum production: <math>Q(20,960) = (20)^{1/4}(960)^{3/4}</math></p>
